ABSTRACT

INTRODUCTION

Ocular surface squamous neoplasia (OSSN) consists of a wide range of conjunctival and corneal lesions ranging from dysplastic lesions to invasive squamous cell carcinoma. In recent times, the incidence of OSSN seems to be on the rise, especially in developing countries. The present study was aimed to analyse demographic pattern, clinical characteristics, and histopathology findings of OSSN in a tertiary care centre of western region of Nepal.

MATERIAL AND METHODS

It was a retrospective study. We analyzed 94 cases of OSSN who presented to cornea department of Lumbini Eye Institute, Bhairahawa, Nepal over a period 1.5 years from 1st July 2017 to 31st December 2018. All the patients with OSSN, detailed clinical history and examination were recorded. Lesions were excised with a 3 mm margin clearance and sent for histopathological examination.

RESULTS

Mean age of our patients with OSSN was 48.89±17.955 years ranging from 17 to 85 years. There were 52 (55.32%) male and 42 (44.68%) female. Mean duration of presentation was 6.34±6.17 months. A solitary nodule at the limbus was the commonest presentation. Right eyes were involved more than left eyes. Lesions were found most commonly on temporal site 52 (55.32%) followed by nasal 36 (38.30%). On histopathological examination benign lesions were found in 31 (32.98%) eyes, preinvasive lesion in 50 (53.19%) eyes and invasive lesions in 13 (13.83%) eyes.

CONCLUSION

OSSN were seen more commonly in young adults with male predominance. Benign and pre invasive lesions are found more commonly than invasive lesions.

INTRODUCTION

Ocular surface squamous neoplasia (OSSN) is a rare clinical entity. It is a broad term encompassing conjunctival intraepithelial neoplastic lesions (CIN) and invasive squamous cell carcinoma (SCC) of conjunctiva and cornea. The average incidence of OSSN of conjunctiva and cornea varies from 0.13/100,000 to 3.5/100,000 population.¹⁻³ In recent years, the incidence of OSSN is increasing in developing countries. OSSN is mostly unilateral and is seen in middle age and older adult patients.⁴ Risk factors associated with the development of OSSN are exposure to ultraviolet (UV)-B light, human immunodeficiency virus (HIV) infection, human papilloma virus (HPV) infection, cigarette smoking, chemicals such as trifluridine or petroleum products, ocular surface injury, vitamin A deficiency and Xeroderma Pigmentosum.⁵⁻⁷ Tumours of the ocular surface have a wide clinical presentation but are usually asymptomatic. OSSN is a low-grade, slow growing malignancy, which rarely metastasize. OSSN usually presents as an elevated conjunctival lesion seen at or near the limbus, grayish-white in colour with a characteristic tuft of blood vessels in the inter palpebral region.

A few patients may present with redness, irritation or foreign body sensation. It is nearly impossible to differentiate OSSN as benign or malignant based on clinical appearance so surgical excision and histopathological examination is always necessary to make correct diagnosis and management. As these tumours are relatively uncommon and data regarding these lesions are relatively scarce from this part of the world so this study was planned to evaluate clinico-demographic characteristics, and histopathology finding of OSSN in a tertiary care centre of western region of Nepal.

MATERIAL AND METHODS

It was a retrospective study conducted on patients aged >15 years and presented to the department of cornea in Lumbini Eye Institute, Bhairahawa, Nepal over a period of 1.5 years from 1st July 2017 to 31st December 2018. Study was ethically approved by the institutional review committee of Lumbini Eye Institute. All the subjects presented with OSSN during the study period were included in the study. We excluded patients <16 years of age. Patients of pterygium, pingecula and limbal dermoid were also excluded.

A detailed history including demographic data of age, sex, occupation, time of presentation, and exposure to risk factors known to cause OSSN were noted in all the patients. A detailed clinical and slit lamp examination was performed to document clinical features of the tumours. High-resolution digital photographs were taken. Clinical features regarding the type of lesion, location and involvement of cornea were documented. Blood investigations like random blood sugar

(RBS), hepatitis B surface antigen (HBsAg) and HIV test were done after obtaining informed consent of the patients. Peribulbar block with 2 % lignocaine was used for local anaesthesia. All lesions were excised by single surgeon with a 3-mm margin clearance, using the 'no touch technique' to minimise tissue handling. Carl Zeiss OPMI VISU 160 operating microscope was used for surgery. After excision tissue were placed directly into buffered formalin and sent for histopathology examination at the histopathology laboratory of the Universal College of Medical Sciences, Bhairahawa, Nepal.

All the histology slides were stained with haematoxylin and eosin and examined by the same pathologist. All the data entered into Microsoft Excel spreadsheet and were analyzed using SPSS ver 16.0(PC) / EpiInfo (CDC, Atlanta, GA, USA). Statistical analysis was done using appropriate test like Chi-square test and a p-value of less than 0.05 was considered significant.

RESULTS

All together 94 patients were presented during the study period and were analyzed. There were 52 (55.32%) male and 42 (44.68%) female. Mean age of our patients was 48.89±17.95 years ranging from 17 to 85 years. There were 51 (54.26%) patients aged ≤50 years and 43 (45.79%) patients aged >50 years. (Table 1)

Table 1. Age distribution

Age group	Frequency(%)
16-20	3 (3.19%)
21-30	18 (19.15 %)
31-40	16 (17.07%)
41-50	14 (14.89%)
51-60	17 (18.09%)
61-70	16 (17.07 %)
71-80	8 (8.51%)
81_90	2 (2.13%)

We had patients from both India and Nepal. There were 48 (51.06%) patients from Nepal including Rupandehi (18), Palpa (6), Nawalparasi (5), Arghakhachi (4), Dang (4), Kapilvastu (4), Gulmi (3), Pyuthan (3) and Kanchanpur (1) districts. From India there were 46 (48.94%) patients from state of Bihar and Uttar Pradesh. There were patients from Maharajgunj (10), Siddharthanagar (8), Deoria (6), Gorakhpur (4) Santa Kabir Nagar (4), Gazipur (3), Balrampur (2), Saran (2), Mau (2), Azamgarh (1), Gaya (1), Jaunpur (1), Kushinagar (1) and Siwan (1) districts. By occupation most of patients were farmer 42 (44.68), followed by housewife 39 (41.49%) students 9 (9.57) and servicemen 4 (4.26%), Mean duration of presentation was 6.34±6.17 months ranging from minimum 1 month to maximum 36 months. History of trauma

was found in only 8 (8.51%) cases. In this series systemic illness was found in 8 (8.51%) patients which included hypertension 3 (3.19%) patients, diabetes mellitus 2 (2.13%) patients, HIV 2 (2.13%) patients and tuberculosis 1 (1.06%) patients. Lesions were found more commonly in right eye 52 (55.32%) followed by left eye in 42 (44.68%).

Figure 1. Some OSSN lesions of eye

Lesions were found most commonly on temporal side of the limbus 52 (55.32%) followed by nasal side 36 (38.30%), inferior side 3 (3.19%), whole 2 (2.13%) and superior part 1 (1.06%) (Figure 1 and 2).

Figure 2. Site of OSSN lesions

On histopathological examination benign lesions were found in 31 (32.98%) eyes, preinvasive lesion in 50 (53.19%) eyes and invasive lesions in 13 (13.83%) eyes. Among benign lesions squamous papilloma was found in 23 (24.47%), epidermoid cyst in 4 (4.26%), conjunctival nevus in 3 (3.19%) and keratoacanthoma in 1 (1.06%) eyes.

Preinvasive lesions were CIN I in 10 (10.64%) eyes, CIN II 8 (8.51%) eyes and CIN III 32 (34.04%) eyes. Invasive squamous cell carcinoma was found in 9 (9.57%) eyes and malignant melanoma in 4 (4.26%) eyes of patients (Figure 3).

Figure 3. Histopathology of few OSSN lesions

DISCUSSION

OSSN are seen more commonly in young adults. Mean age of our patients was 48.89 years ranging from 17 to 85 years which is similar to the study done by Dandala PP et. al. where the mean age of the patients was 45.20 years with age ranging from 18 to 78 years.⁸ In our study, there were 55.32% male so male outnumbered female which are seen in many other studies also.⁹⁻¹² Higher incidence of OSSN in male gender and young adult age group may be associated with increased exposure to ultraviolet rays exposure during outdoor work. Prevalence of OSSN in Africa is higher in female than male.¹³⁻¹⁴ This may be related to Africa having the highest prevalence of both HIV and HPV, which may increase the risk of OSSN in women. By occupation most of patients (44.68%) were farmers, followed by housewives 41.49% which is obvious as this is a agriculture predominant area where living of most of population are based on agriculture related work. These farmers also more exposed with UV lights during outdoor farming activities. Mean duration of presentation was 6.34 months ranging from minimum 1 month to maximum 36 months. In a study done in Delhi, mean duration of symptoms was 1.03 year.¹²

The pathogenesis of OSSN is multifactorial. Various etiological factors are thought to be responsible for OSSN, but it is not clear how they interact and lead to development of OSSN. Factors associated with the development of OSSN are exposure to sunlight, HPV type 16 and 18 infections, HIV infection, ocular surface injury, chemicals such as trifluridine, arsenic, beryllium or petroleum products, vitamin A deficiency Xeroderma pigmentosum, old age, heavy cigarette smoking, male sex, immune-compromised states and light pigmentation of the hair and eye. All these factors lead to genetic injury to a proliferating cell which lead to uncontrolled basic cellular functions like cell division and differentiation and make them neoplastic. There is linear relationship between exposure to ultraviolet radiation and development of OSSN. The degree of risk depends on the type of UV rays, the intensity of exposure, duration of exposure and the quantity of

the light-absorbing protective melanin in a person. Among UV rays, UV B is believed to be responsible for the induction of various cutaneous and ocular surface cancers. Exposure to UV B light leads to the formation of pyrimidine dimers in DNA and it also causes damage to the nucleotide excision repair pathway which plays a key role in repairing DNA damage. HPV is a DNA virus. HPV types 16 and 18 have been implicated in the genesis of several cancers, particularly squamous cell carcinoma of the cervix, anogenital, oropharyngeal and ocular surface regions. There is an increase in the incidence of OSSN, since the emergence of HIV. The rising incidence of OSSN in recent decades may be driven by increased prevalence of these. In this study, history of trauma was found in only 8.51% and HIV in 2.13% patients. These results are similar to study from Delhi where only one patient was found to have HIV. Studies especially from Africa have a higher incidence of HIV and HPV. In these countries OSSN are also found to occur more at younger age group.^{14,15} In a study done by Dandala et al. from Hyderabad, about 23% of the patients tested positive for HIV in whom mean age of presentation was 34 years only.⁸ OSSN lesions occur more often in the interpalpebral area of perilimbal conjunctiva, and can extend across the limbus to involve the cornea. Isolated corneal involvement by OSSN is very rare.

A study in Uganda demonstrated that tumors almost always occur in sun-exposed areas of the eye.¹⁶ It is thought that the human eye is more exposed laterally, making this a large collecting zone of peripheral sunlight. In our study lesions were found most commonly on temporal side 55.32% followed by nasal side 38.30% which is similar to another study where 50.44% had nasal lesions and 49.56% had temporal lesions.⁸ Clinical presentation of CIN and invasive SCC is very similar thus it is very difficult to differentiate them clinically. Usually OSSN presents as a circumscribed, gelatin-like, sessile, papillomatous lesion with variable degrees of leukoplakia. One often finds dilated conjunctival blood vessels feeding and draining the lesion. SCC is locally invasive and metastasis is very rarely seen. Sometimes, OSSN can be diffuse, flat, and poorly-demarcated lesions without an obvious tumour, making early diagnosis difficult. Sometimes, lesions can be massive covering the entire ocular surface area or rarely pigmented which can be difficult to differentiate from conjunctival melanoma. Histopathological evaluation of the lesion after an excisional biopsy is the gold standard for the diagnosis of OSSN. CIN can progress to invasive SCC with destruction of the epithelial basement membrane and extension into the underlying stromal tissue. Differentiation of SCC is in terms of degree of keratinisation termed as well-differentiated, moderately differentiated and poorly differentiated carcinoma. Keratinisation is seen more in well and moderately differentiated tumours with less nuclear pleomorphism. Poorly differentiated tumours have predominance of immature cells with higher nuclear-

cytoplasmic ratio, more pleomorphic nuclei, increased typical and atypical mitoses and minimal keratinization. Other ocular surface lesions which can clinically mimic OSSN such as actinic keratosis, pterygium, pinguecula and actinic granuloma can be easily distinguished from OSSN by studying the morphology. Management modalities in OSSN range from complete excision in well delineated tumours to chemotherapy in diffuse unresectable lesions. Medical alternatives in the form of topical applications 5-Fluorouracil (5FU), mitomycin C (MMC) and Interferon (IFN α 2b) have been extensively reported in the literature. Primary treatment with chemo therapeutic agents for OSSN is largely limited to localized OSSN. Both MMC and 5FU have also been used as adjuvant therapy for recurrent lesions.^{17,18} Owing to a better toxicity profile of IFN α 2b currently seems to be the treatment of choice for wider and extensive OSSN involving >4 clock hours of the limbus.¹⁹ The overall prognosis in OSSN is good. Modern treatment strategies are effective with local recurrence rates reported to be 5% and regional lymph node metastasis at <2%. Aggressive variants like muco-epidermoid and spindle cell carcinoma and OSSN in immunocompromised patients have a worse prognosis. While complete excision with cryotherapy gives excellent results with localized lesions, newer modalities like immunotherapy hold a promise in the larger, un-resectable and recurrent lesions.

CONCLUSION

OSSNs are seen more commonly in young adults with male predominance. Lesions are found most commonly on temporal side followed by nasal side which together make majority of lesions. Benign and preinvasive lesions are found more commonly than invasive lesions. Nodular type of lesion is the commonest variety. On histopathological examination among benign lesions squamous papilloma and among invasive lesions, invasive squamous cell carcinoma were the commonest diagnosis. So, all the OSSN lesions should be evaluated carefully and treated with proper excision with histopathological examination.
